SECTION 1

INTRODUCTION

This conversion subroutine package consists of three subroutines which may be run on any Varian Data Machines 620 series computer. These subroutines enable the user to convert from one character code, usually associated with a particular peripheral device, to the character code of a different device. The three subroutines (described in detail in section 2) are:

EBCDIC TO HOLLERITH CONVERSION
HOLLERITH TO EBCDIC CONVERSION
EBCDIC TO ASCII CONVERSION

The EBCDIC TO HOLLERITH conversion subroutine (SA01) converts an 8-bit EBCDIC character in the A-register to its equivalent 12-bit HOLLERITH code in the A-register.

The HOLLERITH TO EBCDIC conversion subroutine (SB01) converts a 12-bit 029 HOLLERITH character in the A-register to its equivalent 8-bit EBCDIC character in the A-register.

The EBCDIC to ASCII conversion subroutine (SC01) converts an 8-bit EBCDIC character in the A-register to its equivalent 8-bit ASCII code in the A-register. If other than 8-bit ASCII code is desired, this routine may be easily modified (see section 2.3.17, comments for SC01).

The user should note the following characteristics of these subroutines:

- 1) Require VDM 620 series computer with a 16-bit word
- 2) Source statements must be assembled with DAS 8A assembler
- 3) The extended addressing option is not necessary
- 4) The multiply/divide option is not necessary

This subroutine package is referenced by the following VDM Software part numbers:

Source Material - 92H0206-001
Object Material - 92U0206-001
Assembly Listing - 92L0206-001

SHT 4 OF 24

2.1

1. Title: Convert EBCDIC to Hollerith
2. Symbolic Name: SA01
3. Purpose: To convert an EBCDIC character in bits 0 through 7 of the A register to IBM 029 Hollerith code in bits 0 through 11 of the A register.
4. Description: Index register B and the input value in the A register are saved. An index pointer into the SAT2 table is built by shifting out the least significant bit of the EBCDIC input, saving only the low order 7 bits, and adding the beginning address of SAT2 to the result. The two packed Hollerith characters from SAT2 are then loaded into the B register. The original EBCDIC value is checked and, if even, the left half of the packed Hollerith word is saved or, if odd, the right half is saved. An index pointer into the SAT1 table is then built by saving the least significant 3 bits of the saved Hollerith word and adding the beginning address of SAT1. Rows 12, 11, 0 are shifted to their output position and merged with rows 1-7. The B register is restored and the word with the output positions of rows 12, 11, 0, 1-7 is saved. Rows 8 and 9 are now merged with the other rows into the final output value of the Hollerith code and a return is made to the calling program.

SHEET **12** OF **24**

2.2

1. Title: Convert Hollerith to EBCDIC
2. Symbolic Name: SB01
3. Purpose: To convert an 029 Hollerith character in bits 0 through 11 of the A register to its corresponding EBCDIC code in bits 0 through 7 of the A register.
4. Description: Index registers B and X are saved. The B register is initialized to zero and will be used as the field 1 (1-7 punches) pointer. The original Hollerith input is checked to see if row 9 is punched. If punched, bit 11 is set and if not punched, bit 11 is reset. The Hollerith input rows 1-7 are now searched against table SBT1 to determine which of the rows 1-7 (or none) has been punched. More than 1 punch in rows 1-7 results in a return to the calling program with the accumulator set negative. An index into table SBT2 is built by isolating card rows 9, 12, 11, 0 into bit positions 6, 5, 4, 3 and adding the displacement into SBT1 which was determined when a match on rows 1-7 was found. This 7 bit number is added to the beginning address of table SBT2 to obtain the address of the corresponding two EBCDIC characters - one with an 8 punch and one without an 8 punch. The original Hollerith input is now checked to see if row 8 was punched. The appropriate EBCDIC is then right justified in the accumulator, the B and X registers are restored, and a return is made to the calling program.
5. Entry Point: SB01
6. Calling Sequence:
 - P-1 LDA value to be converted
 - P JMPM
 - P+1 SB01
 - P+2 Any instruction
7. Entrance Parameters: 029 Hollerith character in bits 0 through 11 of A register.

2.3

1. Title: EBCDIC to ASCII Conversion
2. Symbolic Name: SC01
3. Purpose: To convert an 8-bit EBCDIC character in the A register to its equivalent 8-bit ASCII code in the A register.
4. Description: Index register B and the input value in the A register are saved. The input value is checked to see if it is in the range of either 40-7F or C0-FF. If not, a return to the calling program is made with the accumulator negative. Otherwise, a shift command to test the validity of the value to be converted is built. The displacement into the SCT1 table is calculated by right justifying bits 4 and 5 of the EBCDIC input. Adding the beginning address of SCT1 to this value yields the address of the word in SCT1 containing the legality bit for this EBCDIC input. A check is now made to determine exactly which range the input value is in, 40-7F or C0-FF. If 40-7F, an offset of zero into the SCT1 table is used. If C0-FF, an offset of four is used. The legality bit for this input value is now checked. If not legal, a return to the calling routine is made with the accumulator negative. If legal, bits 1-5 of the EBCDIC input value are added to the beginning address of the SCT2 table to obtain the address of the word containing the two ASCII characters for this value. If the EBCDIC input value was even, the left ASCII character is set in the accumulator, right justified. If odd, the right ASCII character is set in the accumulator, also right justified. The B register is then restored and a return is made to the calling program.
5. Entry Points: SC01
6. Calling Sequence:

P-1	LDA value
P	JMPM SC01
P+2	Any Instruction

7. Entrance Parameters: EBCDIC character in bits 0 through 7 of A register.
8. Exit Point: Only one exit exists for this subroutine. Return is to P+2 of the calling program.
9. Exit Parameters: B register unchanged.
ASCII code in bits 0 through 7 of the A register.
10. Table or Files Modified or Read: SCT1 Legality check table
SCT2 ASCII character table
11. Tables or Files Created: None
12. Called By: Any system program
13. Called From: None
14. Exception Conditions: If the input value is not in the ranges 40-7F or C0-FF, or if the legality status bit in Table SCT1 is set, a return to the calling program is made with the accumulator set negative.
15. Timing: 17 cycles minimum
72 cycles maximum
16. Size: 44 words - Instructions
2 words - Temporary storage
40 words - Tables
17. Comments: This subroutine is not re-entrant. Some output devices allow only 7-bit ASCII. If other than 8-bit ASCII is desired, this subroutine should be modified as follows:

Either - 1) Modify table SCT2 to include desired codes
or
2) Insert an appropriate mask instruction at location SC30+1.
18. Special Notation: None
19. Hardware Details: None
20. Flowcharts:

SHEET 18 OF 24

SECTION 3

TEST PROCEDURE AND RESULTS

3.1 DESCRIPTION OF PROCEDURE

The three conversion routines were tested as follows:

Two tables, TBL1 and TBL2 were generated. For the EBCDIC TO HOLLERITH conversion, sequential EBCDIC values from 0 to 255 were placed into the A-register and a call to SA01 was made for each value. The output HOLLERITH characters were then placed sequentially into TBL1.

For the HOLLERITH TO EBCDIC conversion, the HOLLERITH values from TBL1 were placed into the A-register and a call to SB01 was made for each value. The output EBCDIC characters were placed sequentially into TBL2. An illegal HOLLERITH character was then given to SB01 with the associated error return stored in TBL2+256.

For the EBCDIC TO ASCII conversion, the EBCDIC values from TBL2 were placed into the A-register and a call to SC01 was made for each value. The output ASCII characters (or error codes) were sequentially stored back into TBL1.
